What is an algorithm?

An **algorithm** is a sequence of unambiguous instructions for solving a problem, i.e., for obtaining a required output for any legitimate input in a finite amount of time.
Euclid’s Algorithm

Problem: Find $\text{gcd}(m,n)$, the greatest common divisor of two nonnegative, not both zero integers $m$ and $n$.

Examples: $\text{gcd}(60,24) = 12$, $\text{gcd}(60,0) = 60$, $\text{gcd}(0,0) = ?$

Euclid’s algorithm is based on repeated application of equality

$$\text{gcd}(m,n) = \text{gcd}(n, m \mod n)$$

until the second number becomes 0, which makes the problem trivial.

Example: $\text{gcd}(60,24) = \text{gcd}(24,12) = \text{gcd}(12,0) = 12$
Two descriptions of Euclid’s algorithm

Step 1  If $n = 0$, return $m$ and stop; otherwise go to Step 2

Step 2  Divide $m$ by $n$ and assign the value of the remainder to $r$

Step 3  Assign the value of $n$ to $m$ and the value of $r$ to $n$. Go to Step 1.

while $n \neq 0$ do
  \[ r \leftarrow m \mod n \]
  \[ m \leftarrow n \]
  \[ n \leftarrow r \]
return $m$
Other methods for computing gcd($m,n$)

Consecutive integer checking algorithm

Step 1  Assign the value of min{$m,n$} to $t$
Step 2  Divide $m$ by $t$.  If the remainder is 0, go to Step 3; otherwise, go to Step 4
Step 3  Divide $n$ by $t$.  If the remainder is 0, return $t$ and stop; otherwise, go to Step 4
Step 4  Decrease $t$ by 1 and go to Step 2
Other methods for \( \gcd(m,n) \) [cont.]

Middle-school procedure

Step 1  Find the prime factorization of \( m \)
Step 2  Find the prime factorization of \( n \)
Step 3  Find all the common prime factors
Step 4  Compute the product of all the common prime factors and return it as \( \gcd(m,n) \)

Is this an algorithm?
Sieve of Eratosthenes

Input: Integer \( n \geq 2 \)

Output: List of primes less than or equal to \( n \)

for \( p \leftarrow 2 \) to \( n \) do \( A[p] \leftarrow p \)

for \( p \leftarrow 2 \) to \( \sqrt{n} \) do

\[ \text{if } A[p] \neq 0 \quad /\text{//} p \text{ hasn’t been previously eliminated from the list} \]

\[ j \leftarrow p \times p \]

while \( j \leq n \) do

\[ A[j] \leftarrow 0 \quad /\text{//} \text{mark element as eliminated} \]

\[ j \leftarrow j + p \]

Example: 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20
Why study algorithms?

- Theoretical importance
  - the core of computer science

- Practical importance
  - A practitioner’s toolkit of known algorithms
  - Framework for designing and analyzing algorithms for new problems
Two main issues related to algorithms

- How to design algorithms
- How to analyze algorithm efficiency
Algorithm design techniques/strategies

- Brute force
- Divide and conquer
- Decrease and conquer
- Transform and conquer
- Space and time tradeoffs
- Greedy approach
- Dynamic programming
- Iterative improvement
- Backtracking
- Branch and bound
Analysis of algorithms

• How good is the algorithm?
  • time efficiency
  • space efficiency

• Does there exist a better algorithm?
  • lower bounds
  • optimality
Important problem types

- sorting
- searching
- string processing
- graph problems
- combinatorial problems
- geometric problems
- numerical problems
Fundamental data structures

- list
  - array
  - linked list
  - string
- stack
- queue
- priority queue
- graph
- tree
- set and dictionary
Analysis of algorithms

Issues:

- correctness
- time efficiency
- space efficiency
- optimality

Approaches:

- theoretical analysis
- empirical analysis
Theoretical analysis of time efficiency

Time efficiency is analyzed by determining the number of repetitions of the *basic operation* as a function of *input size*.

- **Basic operation**: the operation that contributes most towards the running time of the algorithm.

\[
T(n) \approx c_{op} C(n)
\]

- **input size**
- **running time**
- **execution time for basic operation**
- **Number of times basic operation is executed**

## Input size and basic operation examples

<table>
<thead>
<tr>
<th>Problem</th>
<th>Input size measure</th>
<th>Basic operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Searching for key in a list of $n$ items</td>
<td>Number of list’s items, i.e. $n$</td>
<td>Key comparison</td>
</tr>
<tr>
<td>Multiplication of two matrices</td>
<td>Matrix dimensions or total number of elements</td>
<td>Multiplication of two numbers</td>
</tr>
<tr>
<td>Checking primality of a given integer $n$</td>
<td>$n$’size = number of digits (in binary representation)</td>
<td>Division</td>
</tr>
<tr>
<td>Typical graph problem</td>
<td>#vertices and/or edges</td>
<td>Visiting a vertex or traversing an edge</td>
</tr>
</tbody>
</table>
Empirical analysis of time efficiency

- Select a specific (typical) sample of inputs

- Use physical unit of time (e.g., milliseconds)
  or
  Count actual number of basic operation’s executions

- Analyze the empirical data
Best-case, average-case, worst-case

For some algorithms efficiency depends on form of input:

- **Worst case:** $C_{\text{worst}}(n)$ – maximum over inputs of size $n$

- **Best case:** $C_{\text{best}}(n)$ – minimum over inputs of size $n$

- **Average case:** $C_{\text{avg}}(n)$ – “average” over inputs of size $n$
  - Number of times the basic operation will be executed on typical input
  - NOT the average of worst and best case
  - Expected number of basic operations considered as a random variable under some assumption about the probability distribution of all possible inputs
Example: Sequential search

ALGORITHM SequentialSearch(A[0..n − 1], K)

//Searches for a given value in a given array by sequential search
//Input: An array A[0..n − 1] and a search key K
//Output: The index of the first element of A that matches K
//         or −1 if there are no matching elements

i ← 0

while i < n and A[i] ≠ K do
    i ← i + 1
if i < n return i
else return −1

 Worst case

 Best case

 Average case
Types of formulas for basic operation’s count

- Exact formula
  e.g., $C(n) = \frac{n(n-1)}{2}$

- Formula indicating order of growth with specific multiplicative constant
  e.g., $C(n) \approx 0.5 \cdot n^2$

- Formula indicating order of growth with unknown multiplicative constant
  e.g., $C(n) \approx c \cdot n^2$
Order of growth

- Most important: Order of growth within a constant multiple as $n \to \infty$

- Example:
  - How much faster will algorithm run on computer that is twice as fast?
  - How much longer does it take to solve problem of double input size?
Values of some important functions as $n \to \infty$

*Table 2.1* Values (some approximate) of several functions important for analysis of algorithms
Asymptotic order of growth

A way of comparing functions that ignores constant factors and small input sizes

- $O(g(n))$: class of functions $f(n)$ that grow no faster than $g(n)$
- $\Theta(g(n))$: class of functions $f(n)$ that grow at same rate as $g(n)$
- $\Omega(g(n))$: class of functions $f(n)$ that grow at least as fast as $g(n)$
Big-oh notation:

\[ t(n) \in O(g(n)) \]
Fig. 2.2 Big-omega notation: \( t(n) \in \Omega(g(n)) \)
Big-theta notation: $t(n) \in \Theta(g(n))$
Establishing order of growth using the definition

**Definition:** \( f(n) \) is in \( O(g(n)) \) if order of growth of \( f(n) \leq \) order of growth of \( g(n) \) (within constant multiple), i.e., there exist positive constant \( c \) and non-negative integer \( n_0 \) such that

\[
f(n) \leq c \cdot g(n) \text{ for every } n \geq n_0
\]

**Examples:**

- \( 10n \) is \( O(n^2) \)
- \( 5n+20 \) is \( O(n) \)
Some properties of asymptotic order of growth

- $f(n) \in O(f(n))$

- $f(n) \in O(g(n))$ iff $g(n) \in \Omega(f(n))$

- If $f(n) \in O(g(n))$ and $g(n) \in O(h(n))$, then $f(n) \in O(h(n))$

  Note similarity with $a \leq b$

- If $f_1(n) \in O(g_1(n))$ and $f_2(n) \in O(g_2(n))$, then $f_1(n) + f_2(n) \in O(\max\{g_1(n), g_2(n)\})$
Establishing order of growth using limits

\[
\lim_{n \to \infty} \frac{T(n)}{g(n)} = \begin{cases} 
0 & \text{order of growth of } T(n) < \text{order of growth of } g(n) \\
c > 0 & \text{order of growth of } T(n) = \text{order of growth of } g(n) \\
\infty & \text{order of growth of } T(n) > \text{order of growth of } g(n)
\end{cases}
\]

Examples:

- \(10n\) vs. \(n^2\)
- \(n(n+1)/2\) vs. \(n^2\)
L’Hôpital’s rule and Stirling’s formula

L’Hôpital’s rule: If \( \lim_{n \to \infty} f(n) = \lim_{n \to \infty} g(n) = \infty \) and the derivatives \( f’, g’ \) exist, then

\[
\lim_{n \to \infty} \frac{f(n)}{g(n)} = \lim_{n \to \infty} \frac{f'(n)}{g'(n)}
\]

Example: \( \log n \) vs. \( n \)

Stirling’s formula: \( n! \approx (2\pi n)^{1/2} (n/e)^n \)
Example: \( 2^n \) vs. \( n! \)
Orders of growth of some important functions

- All logarithmic functions $\log_a n$ belong to the same class $\Theta(\log n)$ no matter what the logarithm’s base $a > 1$ is.

- All polynomials of the same degree $k$ belong to the same class: $a_k n^k + a_{k-1} n^{k-1} + \ldots + a_0 \in \Theta(n^k)$

- Exponential functions $a^n$ have different orders of growth for different $a$’s.

- Order $\log n < \text{order } n^\alpha$ ($\alpha > 0$) $< \text{order } a^n < \text{order } n! < \text{order } n^n$
### Basic asymptotic efficiency classes

Time efficiency of nonrecursive algorithms

General Plan for Analysis

- Decide on parameter $n$ indicating *input size*
- Identify algorithm’s *basic operation*
- Determine *worst*, *average*, and *best* cases for input of size $n$
- Set up a sum for the number of times the basic operation is executed
- Simplify the sum using standard formulas and rules (see Appendix A)
Useful summation formulas and rules

\[ \sum_{l \leq i \leq u} 1 = 1 + 1 + \cdots + 1 = u - l + 1 \]

In particular, \[ \sum_{l \leq i \leq u} 1 = n - 1 + 1 = n \in \Theta(n) \]

\[ \sum_{1 \leq i \leq n} i = 1 + 2 + \cdots + n = n(n+1)/2 \approx n^2/2 \in \Theta(n^2) \]

\[ \sum_{1 \leq i \leq n} i^2 = 1^2 + 2^2 + \cdots + n^2 = n(n+1)(2n+1)/6 \approx n^3/3 \in \Theta(n^3) \]

\[ \sum_{0 \leq i \leq n} a^i = 1 + a + \cdots + a^n = (a^{n+1} - 1)/(a - 1) \text{ for any } a \neq 1 \]

In particular, \[ \sum_{0 \leq i \leq n} 2^i = 2^0 + 2^1 + \cdots + 2^n = 2^{n+1} - 1 \in \Theta(2^n) \]

\[ \sum(a_i \pm b_i) = \sum a_i \pm \sum b_i \quad \sum ca_i = c\sum a_i \quad \sum_{l \leq i \leq u} a_i = \sum_{l \leq i \leq m} a_i + \sum_{m+1 \leq i \leq u} a_i \]
Example 1: Maximum element

ALGORITHM \textit{MaxElement}(A[0..n - 1])

\begin{description}
\item*[//] Determines the value of the largest element in a given array
\item*[//] Input: An array $A[0..n - 1]$ of real numbers
\item*[//] Output: The value of the largest element in $A$
\end{description}

\begin{verbatim}
maxval \leftarrow A[0]
for i \leftarrow 1 to n - 1 do
    if $A[i] > maxval$
        \textbf{then}
            maxval \leftarrow A[i]
\end{verbatim}

\textbf{return} maxval
Example 2: Element uniqueness problem

**ALGORITHM** \textit{UniqueElements}(A[0..n – 1])

// Determines whether all the elements in a given array are distinct
// Input: An array A[0..n – 1]
// Output: Returns “true” if all the elements in A are distinct
// and “false” otherwise

\begin{verbatim}
for i ← 0 to n – 2 do
  for j ← i + 1 to n – 1 do
return true
\end{verbatim}
Example 3: Matrix multiplication

**Algorithm**  \( \text{MatrixMultiplication}(A[0..n-1, 0..n-1], B[0..n-1, 0..n-1]) \)

//Multiplies two \( n \)-by-\( n \) matrices by the definition-based algorithm

//Input: Two \( n \)-by-\( n \) matrices \( A \) and \( B \)

//Output: Matrix \( C = AB \)

\[
\text{for } i \leftarrow 0 \text{ to } n - 1 \text{ do }
\]

\[
\quad \text{for } j \leftarrow 0 \text{ to } n - 1 \text{ do }
\]

\[
\quad \quad C[i, j] \leftarrow 0.0
\]

\[
\quad \text{for } k \leftarrow 0 \text{ to } n - 1 \text{ do }
\]

\[
\quad \quad C[i, j] \leftarrow C[i, j] + A[i, k] \times B[k, j]
\]

return \( C \)
Example 4: Gaussian elimination

Algorithm GaussianElimination($A[0..n-1,0..n]$)

// Implements Gaussian elimination of an $n$-by-$(n+1)$ matrix $A$

for $i \leftarrow 0$ to $n - 2$ do
  for $j \leftarrow i + 1$ to $n - 1$ do
    for $k \leftarrow i$ to $n$ do

Find the efficiency class and a constant factor improvement.
Example 5: Counting binary digits

**ALGORITHM**  \( Binary(n) \)

//Input: A positive decimal integer \( n \)
//Output: The number of binary digits in \( n \)'s binary representation

\[
\text{count} \leftarrow 1 \\
\text{while } n > 1 \text{ do} \\
\quad \text{count} \leftarrow \text{count} + 1 \\
\quad n \leftarrow \lfloor n/2 \rfloor \\
\text{return } \text{count}
\]

It cannot be investigated the way the previous examples are.
Plan for Analysis of Recursive Algorithms

- Decide on a parameter indicating an input’s size.

- Identify the algorithm’s basic operation.

- Check whether the number of times the basic op. is executed may vary on different inputs of the same size. (If it may, the worst, average, and best cases must be investigated separately.)

- Set up a recurrence relation with an appropriate initial condition expressing the number of times the basic op. is executed.

- Solve the recurrence (or, at the very least, establish its solution’s order of growth) by backward substitutions or another method.
Example 1: Recursive evaluation of $n!$

**Definition:** $n! = 1 \cdot 2 \cdot \ldots \cdot (n-1) \cdot n$ for $n \geq 1$ and $0! = 1$

**Recursive definition of $n!$:** $F(n) = F(n-1) \cdot n$ for $n \geq 1$ and $F(0) = 1$

**ALGORITHM** $F(n)$

//Computes $n!$ recursively
//Input: A nonnegative integer $n$
//Output: The value of $n!$

if $n = 0$ return 1
else return $F(n - 1) \cdot n$

**Size:**

**Basic operation:**

**Recurrence relation:**
Solving the recurrence for $M(n)$

$M(n) = M(n-1) + 1, \quad M(0) = 0$
Example 2: The Tower of Hanoi Puzzle

Recurrence for number of moves:
Solving recurrence for number of moves

\[ M(n) = 2M(n-1) + 1, \quad M(1) = 1 \]

- $n - 2$
- $n - 2$
- $n - 2$
- $n - 2$
- $n - 2$
Example 3: Counting #bits

ALGORITHM  \textit{BinRec}(n)

//Input: A positive decimal integer \textit{n}
//Output: The number of binary digits in \textit{n}'s binary representation

\textbf{if } n = 1 \textbf{ return } 1
\textbf{else return } \textit{BinRec}(\lfloor n/2 \rfloor) + 1
Fibonacci numbers

The Fibonacci numbers:
0, 1, 1, 2, 3, 5, 8, 13, 21, ...

The Fibonacci recurrence:

\[ F(n) = F(n-1) + F(n-2) \]
\[ F(0) = 0 \]
\[ F(1) = 1 \]

General 2nd order linear homogeneous recurrence with constant coefficients:

\[ aX(n) + bX(n-1) + cX(n-2) = 0 \]
Solving \( aX(n) + bX(n-1) + cX(n-2) = 0 \)

- Set up the characteristic equation (quadratic)
  \[ ar^2 + br + c = 0 \]

- Solve to obtain roots \( r_1 \) and \( r_2 \)

- General solution to the recurrence
  
  if \( r_1 \) and \( r_2 \) are two distinct real roots: \( X(n) = \alpha r_1^n + \beta r_2^n \)
  
  if \( r_1 = r_2 = r \) are two equal real roots: \( X(n) = \alpha r^n + \beta nr^n \)

- Particular solution can be found by using initial conditions
Application to the Fibonacci numbers

\[ F(n) = F(n-1) + F(n-2) \] or \[ F(n) - F(n-1) - F(n-2) = 0 \]

Characteristic equation:

Roots of the characteristic equation:

General solution to the recurrence:

Particular solution for \( F(0) = 0, F(1) = 1 \):
Computing Fibonacci numbers

1. Definition-based recursive algorithm

2. Nonrecursive definition-based algorithm

3. Explicit formula algorithm

4. Logarithmic algorithm based on formula:

\[
\begin{pmatrix}
F(n-1) & F(n) \\
F(n) & F(n+1)
\end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}^n
\]

for \( n \geq 1 \), assuming an efficient way of computing matrix powers.
