## Tackling Dififcult Combinatorial Problems

There are two principal approaches to tackling difificult combinatorial problems (NP-hard problems):
\& Use a strategy that guarantees solving the problem exactly but doesn't guarantee to find a solution in polynomial time
\& Use an approximation algorithm that can find an approximate (sub-optimal) solution in polynomial time

## Exact Solution Strategies

o exhaustive search (brute force)

- useful only for small instances
of dynamic programming
- applicable to some problems (e.g., the knapsack problem)
o bucktracking
- eliminates some unnecessary cases from consideration
- yields solutions in reasonable time for many instances but worst case is still exponential
\& branch-anad-bownal
- further refines the backtracking idea for optimivation problems
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 1202012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Backtracking

\& Construct the state-spuce tree

- nodes: partial solutions
- edges: choices in extending partial solutions
\& Explore the state space tree using depth-first search
\& "Prune" nowpromising hodes
- stop exploring subtrees rooted at nodes that cannot lead to a solution and backtracks to such a node's parent to continue the search

[^0]Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Example: $n$-Queens Problem

## Place $\boldsymbol{n}$ queens on an $\boldsymbol{n}$-by- $\boldsymbol{n}$ chess board so that no two of them

 are in the same row, column, or diagonal
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 @2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## State-Space Tree of the 4-Queens Problem

## Example: Hamiltonian Circuit Problem

## 

A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Branch-and-Bound

\& An enhancement of backtracking
\& Applicable to optimization problems
\& For each node (partial solution) of a state-space tree, computes a bound on the value of the objective function for all descendants of the node (extensions of the partial solution)
\& Uses the bound for:

- ruling out certain nodes as "nonpromising" to prune the tree - if a node's bound is not better than the best solution seen so far
- guiding the search through state-space
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Example: Assignment Problem

Select one element in each row of the cost matrix $C$ so that:

- no two selected elements are in the same column
- the sum is minimized

## Example

|  | Job 1 | Job 2 | Job 3 | Job 4 |
| :--- | :---: | :---: | :---: | :---: |
| Person $a$ | 9 | 2 | 7 | 8 |
| Person $b$ | 6 | 4 | 3 | 7 |
| Person $c$ | 5 | 8 | 1 | 8 |
| Person $d$ | 7 | 6 | 9 | 4 |

Lower bound: Any solution to this problem will have total cost at least: $2+3+1+4($ or $5+2+1+4)$

## Example: First two levels of the state-space tree

Figure Levels 0 and 1 of the state-space tree for the instance of the assignment problem being solved with the best-first branch-and-bound algorithm. The number above a node shows the order in which the node was generated. A node's fields indicate the job number assigned to person $a$ and the lower bound value, $l b$, for this node.

## Example (cont.)

Figure Levels 0, 1, and 2 of the state-space tree for the instance of the assignment problem being solved with the best-first branch-and-bound algorithm

## Example: Complete state-space tree

solution

inferior solution

Figure Complete state-space tree for the instance of the assignment problem solved with the best-first branch-and-bound algorithm

## Example: Traveling Salesman Problem

first tour
better tour
inferior tour
optimal tour

## Approximation Approach

Apply a fast (i.e, a polynomial-time) approximation algorithm to get a solution that is not necessarily optimal but hopefully close to it

## Accuracy measures:

accuracy ratio of an approximate solution $s_{a}$ $r\left(s_{a}\right)=\mathrm{f}\left(s_{a}\right) / \mathrm{f}\left(s^{* *}\right)$ for minimivation problems $r\left(s_{a}\right)=f\left(s^{* *}\right) / f\left(s_{a}\right)$ for maximivation problems
where $f\left(s_{a}\right)$ and $f\left(s^{* *}\right)$ are values of the objective function $f$ for the approximate solution $s_{a}$ and actual optimal solution $s^{* *}$
performance ratio of the algorithm $A$
the lowest upper bound of $r\left(S_{a}\right)$ on all instances

[^1]
## Nearest-Neighbor Algorithm for TSP

Starting at some city, always go to the nearest unvisited city, and, after visiting all the cities, return to the starting one

$s_{a}: A-B-C-D-A$ of length 10
$s^{*}: A-B-D-C-A$ of length 8

Note: Nearest-neighbor tour may depend on the starting city

Accuracy: $R_{A}=\infty$ (unbounded above)-make the length of $A D$ arbitrarily large in the above example

## Multifiragment-Heuristic Algorithm

Stage 1: Sort the edges in nondecreasing order of weights. Initialize the set of tour edges to be constructed to empty set

Stage 2: Add next edge on the sorted list to the tour, skipping those whose addition would 've created a vertex of degree 3 or a cycle of length less than $n$. Repeat this step until a tour of length $n$ is obtained

Note: $R_{A}=\infty$, but this algorithm tends to produce better tours than the nearest-neighbor algorithm

## Twice-Around-the-Tree Algorithm

Stage 1: Construct a minimum spanning tree of the graph (e.g., by Prim's or Kruskal's algorithm)

Stage 2: Starting at an arbitrary vertex, create a path that goes twice around the tree and returns to the same vertex

Stage 3: Create a tour from the circuit constructed in Stage 2 by making shortcuts to avoid visiting intermediate vertices more than once

Note: $\mathbf{R}_{A}=\infty$ for general instances, but this algorithm tends to produce better tours than the nearest-neighbor algorithm

[^2]Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Example

Walk: $a-b-c-b-d-c-d-b-a$
Tour: $a-b-c-d-e-a$
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 O2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Christofides Algorithm

Stage 1: Construct a minimum spanning tree of the graph
Stage 2: Add edges of a minimum-weight matching of all the odd vertices in the minimum spanning tree

Stage 3: Find an Eulerian circuit of the multigraph obtained in Stage 2

Stage 3: Create a tour from the path constructed in Stage 2 by making shorteuts to avoid visiting intermediate vertices more than once
$R_{A}=\infty$ for general instances, but it tends to produce better tours than the twice-around-the-minimum-tree alg.

## Example: Christofides Algorithm

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Euclidean Instances

Theorem If $P \neq N P$, there exists no approximation algorithm for ISP with a finite performance ratio.
Definition An instance of TSP is called Euctidean, if its distances satisfiy two conditions:

1. symmetry $\mathrm{d}[i, j]=\mathrm{d}[j ; i]$ for any pair of cities $i$ and $j$ 2. triangle inequality $\mathrm{d}[i, j] \leq \mathrm{d}[i, k]+\mathrm{d}[k, j]$ for any cities $i, j, k$

## For Euclidean instances:

approx. tour length / optimal tour length $\leq 0.5\left(\left[\log _{2} n\right]+1\right)$
for nearest neighbor and multifragment heuristic;
approx. tour length / optimal tour length $\leq 2$
for twice-around-the-tree;
approx. tour length / optimal tour length $\leq 1.5$
for Christofides
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Local Search Heuristics for TSP

Start with some initial tour (e.g, nearest neighbor), On each iteration, explore the current tour's neighborhood by exchanging a few edges in it. If the new tour is shorter, make it the current tour; otherwise consider another edge change. If no change yields a shorter tour, the current tour is returned as the output.

Example of a 2-change

## Example of a 3-change

A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

## 

TABLE 12.1 Average tour quality and running times for various heuristics on the 10,000-city random uniform Euclidean instances [Joh02]

## Heuristic

\% excess over the Held-Karp bound

Running time
(seconds)

| nearest neighbor | 24.79 | 0.28 |
| :--- | ---: | ---: |
| multifragment | 16.42 | 0.20 |
| Christofides | 9.81 | 1.04 |
| 2-opt | 4.70 | 1.41 |
| 3-opt | 2.88 | 1.50 |
| Lin-Kernighan | 2.00 | 2.06 |

A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Greedy Algorithm for Knapsack Problem

Step 1: Order the items in decreasing order of relative values:

$$
v_{1} / w_{1} \geq \cdots \geq v_{n} / w_{n}
$$

Step 2: Select the items in this order skipping those that don't fit into the knapsack

Example: The knapsack's capacity is 16 item weight value $\mathrm{v} / \mathrm{w}$
1
2
$\$ 40$
20
2
3
10
\$30
6

4
5
$\$ 50$
5

## Accuracy

o $\mathrm{R}_{\mathrm{A}}$ is unbounded (e.g., $n=2, C=m, w_{1}=1, v_{1}=2, w_{2}=m, v_{2}=m$ ) yields exact solutions for the continuous version
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 O2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Approximation Scheme for Knapsack Problem

Step 1: Order the items in decreasing order of relative values: $\nu_{1} / w_{1} \geq \cdots \geq v_{n} / w_{n}$
Step 2: For a given integer parameter $k, 0 \leq k \leq n$, generate all subsets of $k$ items or less and for each of those that fit the knapsack, add the remaining items in decreasing order of their value to weight ratios
Step 3: Find the most valuable subset among the subsets generated in Step 2 and return it as the algorithm's output

- Accuracy: $\mathrm{f}\left(s^{*}\right) / \mathrm{f}\left(s_{a}\right) \leq 1+1 / k$ for any instance of size $n$
- Time efficiency: O(kn $\left.h^{k+1}\right)$
- There are fully polynomial schemess algorithms with polynomial running time as functions of both $n$ and $k$

[^3] Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Bin Packing Problem: First-Dit Algorithm

Finst-Fit (FWr) Algorithm: Consider the items in the order given and place each item in the first available bin with enough room for it; if there are no such bins, start a new one

Example: $n=4, s_{1}=0.4, s_{2}=0.2, s_{3}=0.6, s_{4}=0.7$

## Accuracy

\& Number of extra bins never exceeds optimal by more than $70 \%$ (i.e., $\mathrm{R}_{\mathrm{A}} \leq 1.7$ )
\& Empirical average-case behavior is much better. (In one experiment with 128,000 bins, the relative error was found to be no more than $2 \%$.)
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Bin Packing: First-Fit Decreasing Algorithm

Finst-Fit Decreasing (FHFD) Algorithm: Sort the items in decreasing order (i,e, from the largest to the smallest). Then proceed as above by placing an item in the first bin in which it fits and starting a new bin if there are no such bins

Example: $n=4, s_{1}=0.4, s_{2}=0.2, s_{3}=0.6, s_{4}=0.7$

## Accuracy

\& Number of extra bins never exceeds optimal by more than $50 \%\left(1, e_{,}, \mathrm{R}_{\mathrm{A}} \leq 1.5\right)$
\& Empirical average-case behavior is much better, too
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 1202012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Numerical Algorithms

Numerical alrorithms concern with solving mathematical problems such as
\& evaluating functions ( $\left(\operatorname{e}, \mathrm{g}, \sqrt{ } x, e^{x}, \ln x, \sin x\right)$
\& solving nonlinear equations
of finding extrema of functions
\& computing definite integrals

Most such problems are of "continuous" nature and can be solved only approximately

## Principal Accuracy Metrics

\& Absolute error of approximation (of $\alpha^{* 3}$ by $a$ )

$$
\left|\alpha-\alpha^{*}\right|
$$

ภ Relative error of approximation (of $\alpha^{*}$ by $\alpha$ )

$$
\left|\alpha-\alpha^{*}\right| /\left|\alpha^{*}\right|
$$

- undefined for $\alpha^{*}=0$
- often quoted in \%
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Two Types of Errors

## truncation errors

- Taylor's polynomial approximation

$$
e^{x} \approx 1+x+x^{2} / 2!+\cdots+x^{n} / n!
$$

absolute error $\leq M I|x|^{n+1} /(n+1)$ ? where $M I=\max e^{t}$ for $0 \leq t \leq x$

- composite trapezoidal rule
$\int_{a}^{b} f(x) d x \approx(h / 2)\left[f(a)+2 \Sigma_{1 \leq-i \leq-n-1} f\left(x_{i}\right)+f(b)\right], \quad h=(b-a) / n$
absolute error $\leq(b-a) h^{2} M I_{2} / 12$ where $M I_{2}=\max \left|f^{\prime \prime}(x)\right|$ for $\boldsymbol{a} \leq \mathrm{x} \leq \boldsymbol{b}$

## \& rownd-officrrors

A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Solving Quadratic Equation

Quadratic equation $a x^{2}+b x+c=0(a \neq 0)$

$$
x_{1,2}=(-b \pm \sqrt{D}) / 2 a \quad \text { where } D=b^{2}-4 a c
$$

Problems:
\& computing square root
use Newton's method: $x_{n+1}=0.5\left(x_{n}+D / x_{n}\right)$
\& subtractive cancellation
use alternative formulas (see p. 411)
use double precision for $D=\boldsymbol{b}^{2}-4 a c$
\& other problems (overfilow, etc.)

## Notes on Solving Nonlinear Equations

\& There exist no formulas with arithmetic ops. and root extractions for roots of polynomials

$$
a_{n} x^{2 n}+a_{n-1} x^{n-1}+\cdots+a_{0}=0 \text { of degree } n \geq 5
$$

\& Although there exist special methods for approximating roots of polynomials, one can also use general methods for

$$
f(x)=0
$$

\& Nonlinear equation $f(x)=0$ can have one, many, infinitely many, and no roots at all
\& Useful:

- sketch graph of $f(x)$
- separate roots
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 O2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Three Classic Methods

## Three classic methods for solving nonlinear equation

$$
f(x)=0
$$

in one unknown:
\& bisection method
\& method of false position (regula falsi)
\& Newton's method
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 @2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Bisection Method

## Based on

\& Theorem: If $f(x)$ is continuous on $a \leq x \leq b$ and $f(a)$ and $f(b)$ have opposite signs, then $f(x)=0$ has a root on $a<x<b$
\& binary search idea

Approximations $x_{n}$ are middle points of shrinking segments
\& $\left|x_{n}-x^{*}\right| \leq(b-a) / 2^{n}$
\& $x_{n}$ always converges to root $x$ but slower compared to others
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 ©2012 Pearson

## Example of Bisection Method Application

Find the root of

$$
x^{3}-x-1=0
$$

with the absolute error not larger than 0.01

| $n$ | $a_{n}$ | $b_{n}$ | $x_{n}$ | $f\left(x_{n}\right)$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $0.0-$ | $2.0+$ | 1.0 | -1.0 |
| 2 | $1.0-$ | $2.0+$ | 1.5 | 0.875 |
| 3 | $1.0-$ | $1.5+$ | 1.25 | -0.296875 |
| 4 |  |  |  |  |
| 5 |  |  |  |  |
| 6 |  |  |  |  |
| 7 |  |  |  |  |
| 8 | $1.3125-$ | $1.328125+$ | 1.3203125 | -0.018711 |

$x \approx 1.3203125$

## Method of False Position

Similar to bisection method but uses $x$-intercept of line through ( $a, f(a)$ ) and $(b, f(b))$ instead of middlle point of $[a, b]$

Approximations $x_{n}$ are computed by the formula

$$
x_{n}=\left[a_{n} f\left(b_{n}\right)-b_{n} f\left(a_{n}\right)\right] /\left[f\left(b_{n}\right)-f\left(a_{n}\right)\right]
$$

\& Normally $x_{\pi}$ converges faster than bisection method sequence but slower than Newton's method sequence
A. Levitin "Introduction to the Design \& Analysis of Algorithms," 3rd ed., Ch. 12 O2012 Pearson

Education, Inc. Upper Saddle River, NJ. All Rights Reserved.

## Newton's Method

Very fast method in which $x_{n}$ 's are $x$-intercepts of tangent lines to the graph of $f(x)$

Approximations $x_{n}$ are computed by the formula

$$
x_{n+1}=x_{n}-f\left(x_{n}\right) / f^{\prime}\left(x_{n}\right)
$$

## Notes on Newton's Method

\& Normally, approximations $x_{n}$ converge to root very fast but can diverge with a bad choice of initial approximation $x_{0}$
\& Yields a very fast method for computing square roots

$$
x_{n+1}=0.5\left(x_{n}+D / x_{n}\right)
$$

\& Can be generalized to much more general equations
